

Does US law enforcement serve everyone equally?

Jón Jónsson

24 February 2017

In a speech in 1963 arguing that economic growth improves living standards for the disadvantaged as well as the affluent, John F Kennedy said ‘A rising tide lifts all boats’¹. In fact, in the years since we have seen that this is only *partially* true: living standards increase but the increases are spread unequally, with the richest in society gaining the most.

As in economics, so in society as a whole. Inequality is one of the most important problems we face today. Using data from the Guardian I intend to explore racial and age inequalities in people killed by police and other law enforcement agencies in the United States. In exploring the data I hope to answer the following questions:

1. Are some racial groups more likely to be killed by police than others?
2. Are some age groups more likely to be killed by police than others?
3. How does the data differ between states and counties across the United States?
4. Does the data compare favourably or unfavourably between the United States and other developed nations?

My primary data source will be The Counted dataset from the Guardian². This consists of two tables containing around 2,300 observations and fourteen variables. The data is *almost* in a tidy structure and I predict it will be trivial to collect and clean it.

To enable sub-national comparisons I will collect state and county population data from data the US Census Bureau makes available as Excel spreadsheets³. Again, this data, comprising around 3,000 observations and a handful of variables, is in good order and I predict little effort will be required to collect and clean it.

Data on deaths by police in countries around the world is more difficult to come by, but I plan on using data aggregated by the Guardian on six countries⁴. To aid the international comparisons I will collect country population data from the World Bank

API¹. This structure of the API means this will be easy to collect and clean. It consists of a handful of observations and variables.

I anticipate that the main difficulties in collating the data will lie in converting the street address of each death into a latitude and longitude so that they can be assigned to a county. This I will do using Geocodio, a reverse geocoding service².
